

Experimental Apparatus for a Digital Health Literacy Experiment (DRAFT)

Robert Jans

Abstract

In this project we implement an software toolkit needed for an experiment planned by the *Institute of Communication and Health (ICH)*. The institute is part of the *Faculty of Communication Sciences* at the *Università della Svizzera Italiana*. Health communication is a relatively new and multidisciplinary field, which includes the study and use of communication to inform and affect decision making at the individual and community level in order to improve the quality of healthcare [1]. The purpose of the planned experiment is to investigate the digital health literacy of participants in the area of sleeping disorders.

This project seeks to provide the experimental apparatus which will allow the research team to record data and test its hypotheses. The project's main tasks are indexing a predefined set of websites, creating a user interface similar to common search engines that can be configured to selectively show different subsets of the corpus according to the experimental conditions under investigation and setting up an experimental environment allowing to conduct controlled experiments (e.g. prevent participants from accessing non-corpus sites) and to record salient data such as search logs and click-stream.

1 Introduction

1.1 Motivation

Since the beginning of modern science researchers needed special tools in order to conduct experiments. These tools consist mainly in devices for taking measurements and triggering phenomena under controlled conditions. Whereas in the past the experimental apparatuses comprised almost exclusively physical devices, nowadays increasingly more software is involved. The experiment for which the result of my project is going to be used is a case in which the process of setting up the experimental conditions and collecting the result data depends heavily on the software toolkit. It is therefore essential for the software to be robust and reliable.

My personal motivations come from two sides: I have a general interest in science and the scientific method, but in practice, rather than as a scientist, I see myself as a technician, who in the area of software development seeks to build useful applications. In that sense this project perfectly fits my interests, as it involves the creation of software to be used in the context of scientific research.

1.2 Outline

TODO:

2 Requirements

Below is a description of the requirements as defined by the advisor. The requirements include three main tasks as well as eight milestones; the milestones are divided into the categories *Must have*, *should have*, and *Nice to have*.

2.1 Main Tasks

1. Spidering (i.e. creating a full or partial local copy of) a predefined set of websites that provide sleeping disorder information as an experimental corpus.
2. Creating a Google-like search interface to the corpus that can be configured to selectively show/rank different sets of corpus sites, according to the experimental conditions under investigation.
3. Setting up an experimental environment (e.g. using the *SafeExamBrowser*, or using a proxy server) to conduct controlled experiments using the corpus (e.g. to prevent participants from accessing non-corpus sites) and to record salient data (e.g. search logs, click-stream).

2.2 Milestones

1. **(Must have)** A website which simulates a search engine that lets users enter keywords into a search form and returns results (snippets) from a predefined corpus of websites/links, which can then be clicked on / followed.
2. **(Must have)** A result generator and a simple way to configure it (e.g. using a text file) on a per-group basis (i.e. participants in Group 1 receive result from lists R1, R2, and R3; Group 2 participants receive results from R4, R2 and R3).
3. **(Must have)** A report describing the system setup/installation and the architectural design.
4. **(Should have)** A result generator that can detect identical, repeated queries (or minor variations of otherwise identical queries, detectable via stop word removal and stemming) upon which it will generate the same response.
5. **(Should have)** A detailed log engine which allows the experimenter to track key experimental results for each participant, such as search terms entered, the time spent on a given result list and any clicks on results (when, which order).
6. **(Should have)** A visual presentation of the search entry and result section that mimics a known search engine.
7. **(Nice to have)** A result generator that can handle non-related searches using a pass-through to a real search engine.
8. **(Nice to have)** A web interface to the log engine that allows for convenient inspection, analysis, and export of experimental results.

3 Project design

3.1 General architecture

Given the close relationships between the experiment configuration, conduction, and analysis, I decided to include most of the implied functionalities into a single web application, called *HSE (Health Search Engine)*. The user management functionality of HSE allows participants to access only a search interface, while experimenters have access to pages for managing corpora and experiments. If needed, participants can be prevented from accessing non-corpus sites by restricting the browser to a whitelist based on the corpus used for a given experiment. The following subsections briefly describe the usage modalities and the related user interfaces.

3.2 Typical usage workflow

The typical workflow includes four steps: preparing the document corpora, setting up an experiment, running the experiment and finally evaluating the resulting data. **Figure 1** shows this usage scenario. To each usage step corresponds a dedicated user interface.

For preparing the corpora the experimenter provides text files containing the web URL's of the chosen documents. After setting the names for the corresponding document collection, the application takes care of downloading the contents and creating the inverted indices needed for retrieval. Setting up an experiment involves defining test groups and assigning participants to each group. Moreover for each test group it is needed to set the document collections from which the retrieval mechanism will select the results to be displayed to the participants. The groups can be defined either manually or by uploading a configuration file. The U.I. for experiment execution includes a control button for starting, stopping, or resetting an experiment, as well as a tabular display for real time monitoring, showing the current number of queries and clicks for each participant. Starting an experiment enables the participants to log in, and initiates the data collection mechanism; after stopping the experiment, the participants are logged out, and transient data is saved. The experiment evaluation interface allows for quick inspection through data summaries and visualizations. Moreover it allows to export both the raw data and the summaries as files.

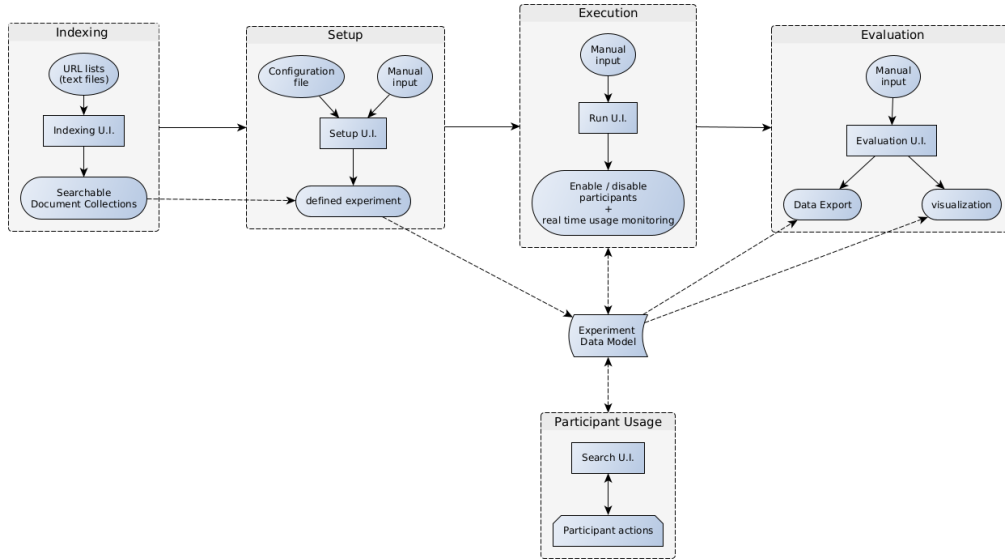

Figure 1. Typical usage workflow

3.3 Search user interface

The interface available to the participants looks similar to the main page of most known search engines. It simply includes a search text bar and a button for entering queries, and displays the results as a list of links accompanied by short summaries (snippets) with highlighted query terms. **Figure 2** shows the U.I. after a query has been entered.
